(57) **ABSTRACT**

A satellite reception assembly may comprise a memory col-located with a receive module and a basestation module. The receive module may receive a satellite signal and recover data carried in the satellite signal. The data may be stored in the memory. The stored data may be transmitted to mobile devices via the basestation module. Which portion of the recovered data is store in the memory may be based on demand for particular data in the coverage area served by the basestation module. Which portion of the recovered data is stored in the memory may be based on information provided by a satellite subscriber, such as the subscriber's anticipated location at one or more future time intervals.

  - U.S. patent application Ser. No. 13/591,768 entitled "Method and System for A Single Frequency Network for Broadcasting to Mobile Devices" and filed on Aug. 22, 2012.
- Each of the above applications is hereby incorporated herein by reference in its entirety.

### TECHNICAL FIELD

Aspects of the present application relate to electronic communications. More specifically, to a method and system for caching content for mobile distribution.

### BACKGROUND

Conventional methods and system for delivering content to mobile devices can be inefficient. Further limitations and disadvantages of conventional and traditional approaches will become apparent to one of skill in the art, through comparison of such approaches with some aspects of the present method and apparatus set forth in the remainder of this disclosure with reference to the drawings.

### BRIEF SUMMARY

A method and/or apparatus is provided for caching content for mobile distribution, substantially as illustrated by and/or described in connection with at least one of the figures, as set forth more completely in the claims.

### BRIEF DESCRIPTION OF THE DRAWINGS

FIGS. 1A and 1B depict a system that is operable to broadcast data to mobile devices.

FIG. 2 depicts an example implementation of the system of FIG. 1 in which the system comprises a small-cell base station.

FIG. 3 depicts an example implementation of the system of FIG. 1 in which the system comprises a macrocell basestation.

FIG. 4 depicts an example system for caching and delivering data.

FIGS. 5A-5C are flowcharts illustrating exemplary steps for caching and delivering data.

FIG. 6A illustrates caching of content based on provided route information and/or location prediction.

FIG. 6B describes an example scenario of content delivery using route-based and/or location predictive content caching.

### DETAILED DESCRIPTION

As utilized herein the terms "circuits" and "circuitry" refer to physical electronic components (i.e. hardware) and any software and/or firmware ("code") which may configure the hardware, be executed by the hardware, and or otherwise be associated with the hardware. As utilized herein, "and/or" means any one or more of the items in the list joined by "and/or". As an example, "x and/or y" means any element of the three-element set {(x), (y), (x, y)}. As another example, "x, y, and/or z" means any element of the seven-element set {(x), (y), (z), (x, y), (x, z), (y, z), (x, y, z)}. As utilized herein, the terms "block" and "module" refer to functions than can be performed by one or more circuits. As utilized herein, the term "exemplary" means serving as a non-limiting example, instance, or illustration. As utilized herein, the term "e.g.," introduces a list of one or more non-limiting examples, instances, or illustrations.

FIGS. 1A and 1B depict a system that is operable to broadcast data to mobile devices. Referring to FIG. 1A, the system 100 comprises a broadcast receive module 104, a wireless input/output (I/O) module 106, a wired I/O module 108, and a routing module 124. Also shown are a service provider network 131, a mobile device 110, a module 112, a client device 122, and a wide area network (WAN) 120.

The satellite 102 may broadcast data (e.g., media content) in accordance with a broadcast standard such as, for example, DVB-S. In an example implementation, some of the bandwidth of the satellite 102 may be utilized for transmitting mobile-formatted content. For example, the content of one or more television networks may be concurrently broadcast in a first format (e.g., high-definition, low-compression ratio video and surround-sound audio) a second format (e.g., standard definition, high-compression ration video and stereo audio). The first format may be encrypted and/or scrambled utilizing a first content protection scheme (e.g., a first set of security algorithms and/or a first set of keys and/or certificates) and the second format may be encrypted and/or scrambled utilizing a second content protection scheme (e.g., a first set of security algorithms and/or a first set of keys and/or certificates). For example, content protected with the first scheme may be recoverable only by devices (e.g., gateways) that have built-in hardware-based conditional access systems (CAS), whereas content protected with the second scheme may be recoverable utilizing keys obtained through two-way exchanges.

The network 131 represents the network(s) of one or more service providers. For example, the network 131 may comprise a network of a cellular service provider, a network of a satellite service provider, and/or a network of a billing service provider that performs billing functions for other service providers. The security and/or billing server 130 may manage billing accounts for subscribers of one or more service providers. For example, the server 130 may maintain a database of users and/or mobile devices which are subscribed to content that is broadcast by the satellite 102 and delivered in a unicast and/or multicast manner via the WAN 120, and may track consumption of the content by those users/devices. This information may be provided to a satellite service provider so that the satellite provider can bill the users/devices for the content. Similarly, the server 130 may maintain a database of users and/or mobile devices which are subscribed to wireless

(e.g., cellular) services associated with the wireless module **106** and may track usage of the module **106**'s bandwidth. This information may be provided to a cellular service provider so that the cellular provider can bill the users/devices for the bandwidth usage.

Additionally or alternatively, the security and/or billing server **130** may manage certificates, keys, and/or other security information for accessing content broadcast by the satellite **102** and/or delivered to the system **100** via the WAN **120** and broadband connection **126**. For example, the server **130** may maintain a database of content currently being transmitted to the system **100** and keys and/or other security information associated with that content. In the example implementation shown in FIG. 1A, the system **100** communicates with the server **130** via the WAN **120**. In the implementation shown in FIG. 1B, on the other hand, the server **130** is reachable wirelessly, via wireless I/O module **132**, such that the system **100** can communicate with the server **130** via a connection **134** without use of the WAN **120** or broadband connection **126**.

The mobile device **110** may be operable to communicate wirelessly in accordance with one or more wireless communication protocols. For example, the device **110** may be a cellular handset operable to communicate in accordance with cellular (e.g., LTE), WiMAX, WiGig, and/or IEEE 802.11 protocols.

The various components of the system **100** and the module **112** may be collocated on, for example, a cellular tower as shown in FIG. 3, on a satellite subscriber premises (e.g., a house, multi-dwelling unit, or business) as shown in FIG. 2, and/or in any other suitable location (e.g., a roadside billboard). The system **100** may comprise one or more printed circuit boards and/or one or more integrated circuits (e.g., one or more silicon die).

The system **100** and the module **112** may be part of a local area network (LAN) and may be interconnected via a LAN technology such as Ethernet (e.g., Ethernet frames communicated over an Ethernet physical layer such as 10/100/1G/10G/40GBASE-T). In an example implementation, each port of the system **100** and the port of module **112** that connects to system **100** may share a common subnet address that is not shared with the port of the module **112** that connects to the WAN **120**. The module **112** may interface the LAN to a wide area network (WAN) **120** over broadband connection **126** utilizing, for example, DOCSIS, DSL, Carrier Ethernet, ATM, Frame Relay, ISDN, x.25, and/or other suitable WAN technology. The WAN **120** may, for example, backhaul traffic between wireless I/O module **106** and a cellular core network.

The broadcast (e.g., satellite broadcast) receive module **104** may be operable to receive broadcast signals and process the received broadcast signals to recover data (e.g., audio content, video content, and/or auxiliary data related to audio and/or video content) carried therein. Although this disclosure focuses on satellite radio and satellite television broadcast signals, the present invention is not so limited. Rather, other types of signals such as terrestrial broadcast television signals are contemplated. Accordingly, various implementations of the system **100** may comprise features described in U.S. patent application Ser. No. 13/546,704, which is incorporated herein by reference, as set forth above. In an example implementation, the receive module **104** may perform channelization such that specific channels, streams, programs, etc. from the receive module **104** can be selectively conveyed to the routing module **124**. In an example implementation, the receive module **104** may output data in the form of MPEG transport stream(s) to the routing module **124**. In an example implementation, the receive module **104** may encapsulate

received data utilizing one or more protocols (e.g., Internet Protocol) for output to the routing module **124**.

The wireless module **106** may be operable to engage in unicast and/or multicast communications with user equipment as represented by the connection **116**. The wireless module **106** may be operable to engage in unicast and/or multicast communications with a service provider, as represented by connection **134**. The wireless module **106** may be operable to broadcast data (e.g., media content), as represented by signal **136**. The wireless module **106** may transmit and/or receive utilizing one or more wireless communication protocols such as, for example, cellular (e.g., LTE), WiMAX, WiGig, and/or IEEE 802.11 protocols. In various example implementations, the wireless module **106** may transmit and/or receive utilizing frequency spectrum owned and/or licensed by a cellular provider, utilizing unlicensed frequency spectrum (e.g., in an Industrial, Scientific, and Medical (ISM) band) and/or utilizing dedicated frequency spectrum owned and/or licensed by the satellite provider affiliated with the satellite **102**. In an example implementation, data may be communicated between the wireless module **106** and the routing module **124** in the form of MPEG transport stream (TS) packets. In an example implementation, data may be communicated between the wireless module **106** and the routing module **124** in the form of Internet Protocol (IP) packets.

In an example implementation, the wireless module **106** may comprise a timing reference module **128** which may enable the wireless module **106** to synchronize timing of its transmissions to a reference clock and/or frequency of its transmissions to a frequency reference signal. For example, the timing reference module **128** may be operable to synchronize to a reference clock and/or frequency reference signal present in received global navigation satellite system (GNSS) signals.

The wired module **108** may be operable to communicate data, via one or more cables **114**, with module **112**. The module **112** (e.g., a media gateway and/or edge router) may, in turn, route traffic between the system **100** and one or more other devices (e.g., client devices, such as client **122**, connected to the gateway and/or interior network nodes connected to the gateway). In an example implementation, the wired I/O module **108** may be operable to output, onto the cable(s) **114**, L-band signals received from the receive module **104**. Such signals may be output in instances that the module **112** is a legacy gateway. Additionally or alternatively, the wired module **108** may be operable to communicate over the cable(s) **114** utilizing Ethernet, Multimedia over Coax Alliance (MoCA), and/or any other suitable protocol(s). In this manner, content may be delivered to the system **100** via the WAN **120** and broadband connection **126**. Such communications may be used, for example, when the module **112** is a gateway that is compatible with an IP-LNB as described in U.S. patent application Ser. No. 13/326,125, which is incorporated by reference herein as set forth above.

In another example implementation, the module **112** may support a wireless connection and the functionality of the wired module **108** may be subsumed by the wireless module **106** and/or by a second wireless module.

The routing module **124** may be operable to selectively route data and/or signals between the modules **104**, **106**, and **108**. The routing may be based, for example, on IP addresses, TCP/UDP port numbers, packet identifiers (PIDs), stream identifiers, and/or any other suitable field or information. For example, packets comprising a first PID (e.g., packets carrying mobile-formatted content) may be sent to the wireless module **106** and packets comprising a second PID (e.g., pack-

ets carrying high-definition content) may be sent to the wired module **108**. In an example implementation, the routing module **124** may be a digital and/or analog crossbar. In an example implementation, the routing module **124** may perform an OSI layer-3 packet-routing function and/or an OSI layer-2 packet-switching function. The routing module **124** may be configured via one or more control signals (not shown) which may, in turn, be based on input (e.g., utilizing a protocol such as DiSEqC) from the module **112** and/or client devices such as the client device **122** and client device **110**.

In operation of an example implementation, the broadcast receive module **104** may receive a satellite signal and perform block down conversion to generate an L-band signal. The L-band signal may be conveyed to the wired module **108** for support of legacy gateways. The receive module **104** may also demodulate the L-band signal to recover one or more MPEG transport streams, channelize the transport stream(s) to recover one or more programs, and encapsulate the transport stream(s) and/or program(s) into one or more packet streams (e.g., utilizing IP or some other suitable protocol(s)). In some instances, the receive module **104** may be operable to decrypt, encrypt, descramble, and/or otherwise process recovered transport stream(s)/program(s) as described in U.S. patent application Ser. No. 13/316,796, which is incorporated by reference herein as set forth above. The one or more packet streams may be conveyed, via routing module **124**, to the wireless module **106** and/or the wired module **108**.

The wired module **108** may decapsulate, encode, modulate, encrypt, and/or otherwise process the transport stream(s) to generate signals suitable for transmission via the cable(s) **114**. The wired module **108** may transmit the generated signals via the cable(s) **114**. Additionally, the wired module **108** may receive signals via the cable(s) **114**, decapsulate, encode, modulate, encrypt, and/or otherwise process the signals to recover content carried in the signals that may have originated from the module **112** and/or been received via the WAN **120** and the broadband connection **126**. The wired module **108** may encapsulate the content into a packet stream and convey the packet stream to the routing module **124**.

The wireless module **106** may encode, modulate, and/or otherwise process packet stream(s) received from the routing module **124** to generate signals suitable for broadcast by the basestation **226**. Thus, the system **100** may enable broadcast of satellite data and/or data delivered to the system **100** via the WAN **120** and broadband connection **126**. For the data received from the satellite **120**, the system **100** may enable delivering the data to the mobile device **110** without the data having to traverse the WAN **120** or the broadband connection **126**. The wireless module **106** may also convey information about the mobile device **110**, and information about the data consumed by the mobile device **110**, to the server **130** for purposes of billing and/or usage tracking.

Broadcasts of data by the wireless module **106** may be synchronized via, the timing reference module **128**, to a received reference clock and/or frequency reference signal. In this manner, the wireless module **106** may be operable to broadcast particular data at the same time and on the same frequency band that the same data is being broadcast by other transmitters (e.g., other instances of the system **100**). The system **100** along with the other transmitters may thus form a single-frequency broadcast network (SFN). As utilized herein, "single frequency" network refers to the fact that particular data may be simultaneously (or nearly so) transmitted by multiple transmitters on the same frequency. Each transmitter, however, is not limited to broadcasting on only a single frequency. Rather, each transmitter may broadcast data on multiple frequencies. Each transmitter that is part of the

SFN may adhere to an electronic programming guide (EPG) that is distributed, for example, via the satellite **102** and/or the server **130**. The EPG may establish which data should be broadcast on which frequency band. In an example implementation, the EPG may assign content and frequency bands on a region-by-region basis such that transmitters in a particular region each broadcast the same data on the same frequency. In this manner, to a device **110** roaming around a particular geographic region, the signals from the various transmitters in the region may simply appear, and be processed, as if they are multipath signals from a single transmitter. Different frequency bands may be utilized in different regions to, for example, account for different spectrum availability in the different regions.

FIG. 2 depicts an example implementation of the system of FIG. 1 in which the system comprises a basestation, such as, for example, a small-cell (e.g., femtocell or picocell) base station. In FIG. 2, the system **100** comprises a satellite reception assembly **202**, and a gateway **214**. The subassembly **204** comprises a feed horn **212**, an IP-LNB module **224**, a cellular basestation module **226**, a routing module **230**, an Ethernet transceiver module **228**, and a wireless transceiver **232**. The various modules of the subassembly **204** may reside in one or more housings, on one or more printed circuit boards, and/or on one or more integrated circuits (e.g., one or more silicon dice). The satellite reception assembly is not, however, limited to implementations comprising a dish. For example, another implementation of the satellite reception assembly **204** may comprise a linear or parabolic array of antenna elements and/or receiver circuits whose signals may be combined for satellite signal reception.

In the example implementation depicted, the satellite reception assembly **202** comprises a parabolic reflector **206** and a subassembly **204** mounted (e.g., bolted or welded) to a support structure **208** which, in turn, comprises a boom **220** and attaches (e.g., via bolts) to the premises **210** (e.g., to the roof). In another example implementation, all or a portion of the modules **224**, **226**, **228**, **230**, and **232** may be mounted to the premises separate from the satellite dish and feed horn (e.g., connected via wired and/or wireless connections), but may still be part of the "outdoor unit." In another example implementation, all or a portion of the modules **224**, **226**, **228**, **230**, and **232** may be part of the gateway **214** (or "indoor unit").

The IP-LNB module **224** may be an implementation of the receive module **104** described above and may be as described in U.S. patent application Ser. No. 13/326,125, which is incorporated herein by reference, as set forth above. The nomenclature "IP-LNB" indicates that the module **224** possesses capabilities beyond the block downconversion of received satellite signals that is performed by conventional LNBs. Functions performed by the IP-LNB module **224** may comprise, for example, downconverting received satellite signals, demodulating received satellite signals, channelizing received satellite signals, and/or encapsulating data recovered from received satellite signals into IP packets.

The routing module **230** may be an implementation of the routing module **124** described above. Functions performed by the routing module **230** may comprise routing of data between the IP-LNB module **224**, the cellular basestation module **226**, and the Ethernet transceiver module **228**. Although an implementation in which the routing module supports IP-based routing is described herein, any suitable protocols (e.g., Ethernet, PCIe, USB, etc.) can be utilized for communication of data between modules **224**, **226**, **228**, **230**, and **232**.

The Ethernet transceiver module **228** may be an implementation of the wired module **108** described above. Functions performed by the module **228** may comprise encapsulation of data from the routing module **230** into Ethernet frames and transmission of the Ethernet frames onto the cable(s) **114** in accordance with Ethernet protocols. Additionally or alternatively, functions performed by the module **228** may comprise reception of Ethernet frames via the cable(s) **114**, processing of the Ethernet frames to recover data carried therein (e.g., IP packets), and conveyance of the recovered data to the routing module **230**.

The combination of the small-cell basestation module **226** and the wireless module **232** may be an implementation of the wireless module **106** described above. Functions performed by the basestation module **226** may comprise communication with cellular-enabled user-equipment (e.g., handsets, tablets, and/or laptops) that are within communication range of the basestation **226**. The basestation module **226** may be operable to receive data via one or more cellular connections **116**, process the received data, and output the data to the routing module **230** in the form of one or more IP packets. Similarly, the small-cell basestation **226** may be operable to receive IP packets from the routing module **230**, process the IP packets, and transmit signals carrying the IP packets (or their contents) via one or more connections **116**.

Functions performed by the wireless module **232** may comprise accessing the security and/or billing server **130** via the wireless connection **134** between the wireless module **106** of the system **100** and the wireless module **132** which provides wireless connectivity to the server **130**. The amount of bandwidth needed for communicating billing and/or security information over the connections **116** and **134** may be small relative to the amount of bandwidth needed for the broadcast signals **136**. Accordingly, in an example implementation, the module **226** may utilize, for example, 4<sup>th</sup> generation protocols such as LTE whereas the wireless module **232** may utilize, for example, 2.5 or 3<sup>rd</sup> generation protocols such as EDGE, HSPA, or EVDO.

The gateway **214** may be an implementation of module **112** described above. Functions performed by the gateway **214** may comprise reception, processing, and transmission of data. The gateway **214** may transmit and/or receive data to and/or from the system **100** (via cable(s) **114**), the WAN **120** (via WAN connection **126**), and/or one or more client devices **122** (via one or more connections **234**). For data from the module **228** to a client device **122**, the gateway **214** may recover the data from Ethernet frames received over the cable(s) **114** and output the data to the client device **122**. For data from the client device **122** and/or gateway **114** to the module **228**, the gateway **214** may encapsulate the data in one or more Ethernet frames and output the frames onto the cable(s) **114**. For data between the WAN **120** and the module **228**, the gateway **214** may perform OSI layer-2 switching and/or OSI layer-3 routing. Although the implementation shown in FIG. 2 uses wired connections between the gateway **214** and module **228**, and between the gateway **214** and WAN **120**, other may utilize wireless connections. Although the gateway **214** is depicted as separate from the system **100**, in other implementations at least a portion of the system **100** may reside in and/or be implemented by the gateway **214**.

In operation, the IP-LNB module **224** may process received satellite signals to recover content carried on one or more satellite channels. In an example implementation, content on one or more of the channels may be formatted for consumption by mobile devices. The content may be cached locally (as described below with reference to FIGS. 4-6B) and conveyed to the routing module **230**. Additionally or alternatively,

mobile-formatted content received from the gateway **214** (such content may have, for example, originated in a digital video recorder of the gateway **214** and/or been received via the WAN **120**) may be conveyed to the routing module **230** via the Ethernet transceiver **228**. The routing module **230** may convey the mobile-formatted content to the small-cell basestation module **226**.

The system **100** may allocate the content among frequencies that are available for transmitting the content. For example, where the content comprises a plurality of television networks, each network may be broadcast on a different frequency according to an EPG provided to the system **100** (e.g., by the satellite **102** and/or by the server **103**). Similarly, where the content comprises a plurality of programs, each program may be broadcast on a different frequency according to an EPG provided to the system **100**.

The mobile device **110** within the coverage area of the basestation module **226** may request satellite content (e.g., a particular TV network or program) via the connection **116**. In response to the request for content, the system **100** may communicate with the server **130** to provide information to the server **130** such that the server can determine whether the mobile device **110** is authorized to receive the requested content, and to provide information to the server **130** so that that an account associated with the mobile device **110** can be billed for the requested content and/or for the bandwidth utilized in receiving the content. The system **100** may communicate with the server **130** via the connection **134**. Additionally or alternatively, the system **100** may communicate with the server **130** via the module **228**, cable **114**, gateway **214**, and WAN **120**.

Upon the server **130** determining that the mobile device **110** is authorized to receive the content that it is requesting, decryption/descrambling keys, an EPG, and/or other information necessary for receiving the requested content may be transmitted to the device **110** via connections **134** and **116**. The mobile device **110** may then tune to the frequency of the desired content, receive the broadcast content, descramble and/or decrypt the received content, and present the content to its user.

In this manner, for satellite content received via the IP-LNB **224**, such satellite content may be delivered to the mobile device **110** without the content having to traverse the WAN **120** or the connection **126**. Thus, in instances that the system **100** communicates with the server **130** via connection **126** and WAN **120**, satellite content may be delivered to the mobile device **110** while only adding a small amount of billing and/or security traffic to the WAN **120**. Moreover, in instances that the system **100** communicates with the server **130** via connection **134**, satellite content may be delivered to mobile device **110** without putting any load on the connection **126** or WAN **120**, thus enabling delivery of the satellite content even when the broadband connection **126** and/or WAN **120** are unavailable.

In an example implementation, the mobile device **110** may belong to a first satellite subscriber and the satellite reception assembly **302** may be installed at the home of a second satellite subscriber. Thus, aspects of the present disclosure may enable the first subscriber to receive satellite content to which he has subscribed via another subscriber's satellite reception assembly.

FIG. 4 depicts an example system for caching and delivering data. In the example implementation of the system **100** shown in FIG. 4, the system **100** comprises the modules **104**, **106**, **124**, and **108** described above. The implementation of system **100** in FIG. 4 also comprises a data caching module **402**.

The data caching module **402** may, for example, comprise memory (e.g., magnetic and/or solid state memory) suitable for storing media content, website content, and/or other data. In an example implementations, the caching module **402** may reside in a next-generation LNB assembly, such as assembly **204** (FIG. 2) or **304** (FIG. 3). In an example implementation, the caching module **402** may be housed separately but collocated with a satellite reception assembly such as assembly **202** or **302** (e.g., mounted in or to the same house, business, or cell tower and connected to the satellite reception assembly via a wired or wireless connection).

In various example implementations, all or a portion of the system **100** may be mounted to the premises separate from the satellite dish and feed horn (e.g., connected via wired and/or wireless connections), but may still be part of the “outdoor unit.” In another example implementation, all or a portion of the modules **224**, **226**, **228**, **230**, and **232** may be part of the gateway **214** (or “indoor unit”).

In operation, media data received via one or more of the modules **104**, **106**, and **108** may be stored in the cache module **402** for later transmission via one or both of the modules **106** and **108**. Which data is cached may be determined based on, for example, past, current, and/or expected demand for particular data in particular areas; characteristics of devices (and/or subscribers associated therewith) that are, were, and/or will be connected to the wireless module **106** and/or to the wired module **108**; and/or past, current, and/or an expected number of devices that are, or will be, connected to the module **106** and/or the module **108**.

Data cached on systems **100** may comprise data delivered via satellite (e.g., satellite **102**) and/or data delivered via the WAN **120** (e.g., the Internet). Data that is cached in particular instances of system **100** may be, for example, based on which content is available in local spot beam incident on the particular instance of system **100**, based on which providers have reached an agreement with an operator of the particular instance of system **100**, based on popularity of particular content in the area served by the particular instance of system **100**, and/or based on any algorithm that attempts to cache content in locations where doing so will improve network efficiencies and/or increase revenues for content providers and/or service providers. Instances of the system **100** may cache: individual movies, catalogs of movies, single episodes of shows, entire seasons of shows, individual audio tracks, entire albums, or any combination thereof. Cached content may be broadcast and/or delivered on-demand in multicast and/or unicast format.

In an example implementation, web-based content which otherwise may only be available to the system **100** via the WAN **120** may be transmitted by the satellite **102**. For example, web-based content that is popular in a particular area may be beamed up to the satellite **102** and then transmitted down to instances of the system **100** via one or more local spot beams. The use of the local spot beams may enable rapid caching of the content on the instances of the system **100** without loading down the WAN **120**. Moreover, where the system **100** is operable to capture an entire satellite band (e.g., a band of ~1 GHz), large amounts of content may be cached to the system **100** in a very short amount of time such that the reallocation of the spot beam(s) to transmitting web-based content only takes a very short amount of time and/or occurs infrequently (e.g., at off-peak times when one or more local television networks is off air).

Various example caching scenarios are described below with respect to FIGS. 5A-5C.

The example steps in FIG. 5A begin with step **502** in which a content provider (e.g., a satellite provider) determines that

there is, or will be, high demand for particular content in a coverage area served by the system **100**. In step **504**, the system **100** in the high-demand location receives and stores the high-demand content in its cache module **402**. In step **506**, mobile devices within the coverage area of the system **100** that request the high-demand content are delivered the cached content via the module **106** rather than via the WAN **120**.

The example steps in FIG. 5B begin with step **512** in which advertising content is received by the system **100** via its module **106** and/or its module **108**. In step **514**, the advertising content may be stored in the cache **402** of the system **100**. In step **516**, the system **100** may insert the cached advertisement into one or more media streams being transmitted via the module **106** and/or via the module **108**. Different ads may be sent via the module **106** than the module **108**. Similarly, different ads may be sent in media streams going to different mobile devices. Which advertisements are cached in the system **100** and/or which advertisements are inserted into which media streams and/or delivered to which devices may be, for example, determined based on negotiations between content providers and the provider who owns and/or operates the system **100**, and/or based on targeted advertising methods such as is disclosed in U.S. patent application Ser. No. 11/928,203, which is incorporated herein by reference, as set forth above.

The example steps in FIG. 5C begin with step **522** in which the mobile device **100** connects to the system **100** and requests particular content (e.g., a particular movie, episode of a television show, whatever is currently playing on a particular television network, a particular webpage, etc.). In step **524**, the system **100** determines whether the requested content is stored in its cache. In not, then the steps may proceed to step **526**.

Returning to step **524**, if the content is cached in the module **420**, then in step **528**, the system **100** determines whether the cached content is up-to-date or whether it is stale. The determination of whether the content is stale may be via a low-bandwidth and/or low-latency signaling between the system **100** and the content provider either via the module **108** or the module **106**. If the content is not stale, then in step **532** the system **100** may transmit the cached content to the mobile device **110**.

Returning to step **528**, if the content is stale then, in step **526**, the system **100** may receive the requested content. If the content is available via satellite, the module **104** may be configured to receive the requested content from the satellite **102** and output the content to the module **124**. If the content is available via the WAN **120** (e.g., the Internet), the system **100** may send a request for the content out to the provider via the WAN **120** and receive the content via the module **108**.

After step **526**, the steps proceed to step **536** in which the content received via the module **104** and/or the module **108** is conveyed, by module **124**, to the module **106** for transmission to the mobile device **110**. After step **526**, the steps conclude with step **540**.

In parallel with step **526** are the steps **534** and **538**. In step **534** the system **100** determines whether to cache the received content in the module **402**. The determination may be, for example, based on the popularity of the content. For example, if the system **100** has received multiple requests for the particular content and/or past traffic patterns indicate the content will be requested again, the system **100** may store the content to module **402** to avoid having to receive the content again in the future. If the system **100** decides to cache the content, then the steps proceed to step **538** in which the content is stored to the module **402**.

11

FIG. 6A illustrates caching of content based on provided route information and/or location prediction. In FIG. 6A, a satellite subscriber plans to travel from location 606 to 608 with in his/her vehicle 606 which comprises a navigation/entertainment system operable to receive content from instances of the system 100. That is, the navigation/entertainment system may be enabled to receive content broadcast on a connection 116, and/or content transmitted over a unicast or multicast connection 134 using any suitable wireless technology (e.g., cellular, Wi-Fi, WiMAX, WiGig, etc.). In another implementation, the subscriber may travel with a mobile device (e.g., a handset or tablet) operable to receive content from instances of the system 100. That is, the handset or tablet may be enabled to receive content broadcast on a connection 116, and/or content transmitted over a unicast or multicast connection 134 using any suitable wireless technology (e.g., cellular, Wi-Fi, WiMAX, WiGig, etc.).

Along the route 604 are six instances of the system 100. The system 100<sub>1</sub> has a coverage area 602<sub>1</sub>, system 100<sub>2</sub> has a coverage area 602<sub>2</sub>, system 100<sub>3</sub> has a coverage area 602<sub>3</sub>, system 100<sub>4</sub> has a coverage area 602<sub>4</sub>, system 100<sub>5</sub> has a coverage area 602<sub>5</sub>, and system 100<sub>6</sub> has a coverage area 602<sub>6</sub>. As the subscriber travels along route 604 from location 606 to location 608 (indicated by a heavy dashed line), he is in each of the coverage areas for some portion of the trip. Example details of how content is delivered to the subscriber as s/he travels from location 606 to location 608 are described below with reference to FIG. 6B.

FIG. 6B describes an example scenario of content delivery using route-based and/or location predictive content caching. The steps begin with step 620 in which the subscriber decides to take a trip from location 606 to location 608 at a particular time.

In step 622, the subscriber may upload the planned trip to a server which handles route-based caching and delivery of content. The trip may, for example, be uploaded via a vehicle navigation system and/or via a web interface accessed on a mobile device. The subscriber may also upload a list of content that s/he would like to consume during the trip.

In step 624, if the user has not manually selected a desired route from location 606 to location 608 trip, the server may calculate a route based on any one or more parameters such as traffic considerations, distance considerations, where instances of the system 100 are located (e.g., which route has the best coverage), subscription models associated with the instances of the system 100, resource availability in the instances of the system 100, etc. For purposes of illustration, it is assumed the route 604 is selected either manually by the subscriber or selected by the server based on input from the subscriber and/or other parameters. The route may be stored in the server for use in coordinating caching and delivery of content during the trip and may be downloaded to the user's navigation system, in the case of a vehicle, or a map application, in the case of a handset or tablet, for example.

In step 626, the server, utilizing the uploaded route information and list of desired content, may selectively cache content on the instances of the system 100 that provide coverage along the route 604. In an example implementation, only portions of content that are likely to be consumed while in a particular coverage area may be downloaded to the instance of system 100 associated with that coverage area. For example, if, based on the planned route, traffic, etc., the subscriber will be in coverage area 602<sub>1</sub> from 12:00 until 12:15 and in coverage area 602<sub>2</sub> from 12:15 until 12:30, then only the portion of the desired content that the subscriber will consume from 12:00 until 12:15 may be cached on the system 100<sub>1</sub> and only the portion of the desired content that the

12

subscriber will consume from 12:15 until 12:30 may be cached on the system 100<sub>2</sub>. In this manner, the amount of data cached on each system 100 may be reduced relative to having to cache all of the desired content on all instances of system 100 along the route 604. There may be some overlap in the cached data to account for unforeseen delays and/or to accommodate seamless handoff without the content being interrupted.

To further illustrate, consider an example scenario where the subscriber will be in each of the coverage areas 602<sub>1</sub>-602<sub>6</sub> for an equal amount of time and would like to watch a movie that is exactly as long as the trip. In such an idealized scenario,  $\frac{1}{6}$  of the movie may be cached on each of the systems 100<sub>1</sub>-100<sub>6</sub>, with the first  $\frac{1}{6}$ <sup>th</sup> being cached on system 100<sub>1</sub>, the second sixth being cached on system 100<sub>2</sub>, and so on.

In addition to (or alternatively to) caching on the systems 100 being planned based on the route information, bandwidth, frequency allocations, and/or other resources of the systems 100<sub>1</sub>-100<sub>6</sub> may be planned based on the route information. For example, a certain amount of bandwidth necessary for delivering the desired content may be reserved on each of the systems 100<sub>1</sub>-100<sub>6</sub> for the respective time period in which the subscriber will be in that system's coverage area. Additionally or alternatively, which channels are reserved for providing the reserved bandwidth may depend on the planned route (e.g., which of the systems 100<sub>1</sub>-100<sub>6</sub> will be handing off to which other of the systems 100<sub>1</sub>-100<sub>6</sub>), local restrictions, spectrum licenses, other trips planned for other devices, and/or any other suitable parameter(s).

In step 628, the subscriber begins the trip. While in each coverage area 602<sub>i</sub> (i being an integer between 1 and 6), the content cached on system 100<sub>i</sub> is transmitted to the subscriber's device. During the trip, the subscriber's position and/or velocity (e.g., reported to the systems 100<sub>1</sub>-100<sub>6</sub> via a low-bandwidth connection) may reported by the subscriber's device and may be used for adjusting caching, reservation of resources, allocation of channels, etc. For example, as it is determined that a portion of the content will be viewed on system 100<sub>i</sub> rather than via system 100<sub>i+1</sub>, the system 100<sub>i+1</sub> may flush that portion of the content from memory to make room for other data. During the trip, the subscriber's position and velocity may also be used in preparing for hand-off's from system 100<sub>i</sub> to system 100<sub>i+1</sub> such that the subscriber receives the content as interruption free as possible. An illustrative scenario is described in the following paragraph.

At time T<sub>0</sub>, a first subscriber's device may be receiving content from system 100<sub>i</sub> on channel 1. Using the first subscriber's pre-uploaded route and current position and velocity, it may be determined (e.g., by a particular one of systems 100<sub>1</sub>-100<sub>6</sub> and/or by a centralized management entity that manages/coordinates the systems 100<sub>1</sub>-100<sub>6</sub>) that the first subscriber's device will be handed-off from system 100<sub>i</sub> to 100<sub>i+1</sub> at time T<sub>1</sub>. At time T<sub>1</sub>-Δ, the system 100<sub>i+1</sub> receives a request for bandwidth from a second subscriber's device. If the second subscriber device needs the bandwidth for period of time less than Δ, channel 1 on the system 100<sub>i+1</sub> may be allocated to the second subscriber's device. Conversely, if the second subscriber's device needs the bandwidth for a period of time longer than Δ, a channel other than channel 1 may be allocated to the second subscriber's device such that channel 1 on the system 100<sub>i+1</sub> is available for handling the first subscriber's device beginning at time T<sub>1</sub>. In this manner, the first subscriber's device does not need to change channels upon being handed off to system 100<sub>i+1</sub>.

Other implementations may provide a non-transitory computer readable medium and/or storage medium, and/or a non-transitory machine readable medium and/or storage medium,

## 13

having stored thereon, a machine code and/or a computer program having at least one code section executable by a machine and/or a computer, thereby causing the machine and/or computer to perform the steps as described herein for caching content for mobile distribution.

Accordingly, the present method and/or apparatus may be realized in hardware, software, or a combination of hardware and software. The present method and/or apparatus may be realized in a centralized fashion in at least one computing system, or in a distributed fashion where different elements are spread across several interconnected computing systems. Any kind of computing system or other apparatus adapted for carrying out the methods described herein is suited. A typical combination of hardware and software may be a general-purpose computing system with a program or other code that, when being loaded and executed, controls the computing system such that it carries out the methods described herein. Another typical implementation may comprise an application specific integrated circuit or chip.

The present method and/or apparatus may also be embedded in a computer program product, which comprises all the features enabling the implementation of the methods described herein, and which when loaded in a computer system is able to carry out these methods. Computer program in the present context means any expression, in any language, code or notation, of a set of instructions intended to cause a system having an information processing capability to perform a particular function either directly or after either or both of the following: a) conversion to another language, code or notation; b) reproduction in a different material form.

While the present method and/or apparatus has been described with reference to certain implementations, it will be understood by those skilled in the art that various changes may be made and equivalents may be substituted without departing from the scope of the present method and/or apparatus. In addition, many modifications may be made to adapt a particular situation or material to the teachings of the present disclosure without departing from its scope. Therefore, it is intended that the present method and/or apparatus not be limited to the particular implementations disclosed, but that the present method and/or apparatus will include all implementations falling within the scope of the appended claims.

What is claimed is:

1. A satellite system comprising:

a plurality of satellite reception assemblies, each comprising a receive module, a memory, and a basestation module; and

one or more servers, wherein:

said one or more servers are operable to receive information indicating a starting point and destination of a trip that a satellite subscriber plans to take in the future, and indicating which satellite television content said satellite subscriber desires to receive during said trip;

said one or more servers are operable to calculate a route for said trip based on at least a portion of said received information and on locations of said plurality of satellite reception assemblies;

## 14

said receive module of one of said plurality of satellite reception assemblies positioned along said calculated route is operable to receive a satellite signal and recover said satellite television content from said satellite signal;

said memory of said one of said plurality of satellite reception assemblies positioned along said calculated route is operable to store at least a portion of said satellite television content;

which portion of said satellite television content is stored in said memory of said one of said plurality of satellite reception assemblies positioned along said calculated route is based on said received information;

said basestation module of said one of said plurality of satellite reception assemblies positioned along said calculated route is operable to transmit said stored portion of said satellite television content to a client device of said satellite subscriber during said trip; and which portion of said recovered satellite television content is stored in said memory of said one of said plurality of satellite reception assemblies is based on an expected amount of demand for particular data in a coverage area served by said basestation module of said one of said plurality of plurality of satellite reception assemblies such that resources are allocated for high-demand content.

2. The satellite system of claim 1, wherein said one of said plurality of satellite reception assemblies comprises a rigid support structure to which said receive module and said basestation module are mounted.

3. The satellite system of claim 2, wherein a parabolic reflector and a feed horn are mounted to said rigid support structure.

4. The satellite system of claim 2, wherein said rigid support structure is adapted for mounting said one of said plurality of satellite reception assemblies to a satellite subscriber premises or to a cellular tower.

5. The satellite system of claim 1, wherein:

said one of said plurality of satellite reception assemblies is connected to a gateway that routes traffic between said one of said plurality of satellite reception assemblies and a wide area network connection terminated at said gateway; and

in being conveyed from said receive module to said basestation module, said satellite television content does not traverse said wide area network connection.

6. The satellite system of claim 1, wherein which portion of said satellite television content is stored in said memory of said one of said plurality of satellite reception assemblies is based on a current position and/or velocity of a mobile device of said satellite subscriber.

7. The satellite system of claim 6, wherein resources of said one of said plurality of satellite reception assemblies are allocated to serving said satellite television content to said satellite subscriber based on said calculated route.

8. The satellite system of claim 1, wherein said satellite signal is a satellite spot beam temporarily allocated to transmission of said satellite television content.
